FOREWORD

It is my immense pleasure to compliment the Bangladesh Bureau of Statistics (BBS) on publishing the report on 'Upazila Level Prevalence of Participation in Organized Learning and Child Marriage in Bangladesh' using Multiple Indicator Cluster Survey (MICS) 2019 data. The MICS 2019 estimates prevalence of these indicators for the whole country, each division and each district. However, there is a rising demand for the estimates of these indicators at a smaller delineation by the policymakers in planning and monitoring the effectiveness of the policies and programmes.

The estimates of organized learning and child marriage has been shown at the appropriate level of disaggregation. This analysis includes an investigation using Small Area Estimation (SAE) methods of how accurately the estimates of organized learning and child marriage may be disaggregated while maintaining an appropriate precision level.

I would like to thank Mr. Mohammed Mizanur Rahman, Director General of BBS for providing timely support and guidance to the successful completion of the activity. Special thanks to Mr. Md. Mashud Alam, Director, Demography and Health Wing, BBS and his team for their hard work and dedication for completing this report. All the distinguished members of the Programme Implementation Committee (PIC), Working Committee, Report Review Committee and Editor's Forum also deserve special thanks.

I deeply acknowledge the support of UNICEF Bangladesh in the execution of this activity. I would like to express my thanks to Dr. Syed Shahadat Hossain, Professor, Institute of Statistical Research and Training (ISRT), University of Dhaka for his technical inputs and support to finalize the report.

Finally, I expect that the findings depicted in the report will be pivotal for planners, policymakers and other stakeholders in formulating policies in Bangladesh.

April, 2024

Dr. Shahnaz Arefin, *ndc*

Director General

Bangladesh Bureau of Statistics (BBS)

PREFACE

Small Area Estimation (SAE) provides information on smaller delineation. It helps policymakers in planning and monitoring the effectiveness of their policies and programmes. This necessity has been intensified due to the fact that the Government is mandated to a perpetual tracking and monitoring of the indicators of the SDG towards 2030. Considering the situation Bangladesh Bureau of Statistics (BBS) has done the SAE for selected indicators.

According to MICS 2019, Bangladesh showed improvement in increasing participation in organized learning from 13.4% in 2012 to 77.4% in 2019. Moreover, Bangladesh achieved a reduction in child marriage from 62% in 2012 to 53% in 2019. Despite these improvements, it is necessary to estimate the prevalence of these indicators at lower-level geographical areas so that more vulnerable areas can be targeted. This report has taken this attempt through the technique of SAE.

I would like to express my gratitude to Secretary of Statistics and Informatics Division, Ministry of Planning for providing guidance and valuable support to complete this technical report. Special thanks to the distinguished members of the Programme Implementation Committee (PIC), Working Committee and other related committees for their contribution to prepare the report.

Furthermore, my sincere appreciation to Mr. Md. Mashud Alam, Director, Demography and Health Wing, BBS and his team for their hard work and dedication for completing this report. I would also like to extend my thanks to Dr. Syed Shahadat Hossain, Professor, Institute of Statistical Research and Training (ISRT), University of Dhaka and Mr. Md. Mynul Islam, Assistant Professor, ISRT, University of Dhaka for their technical inputs in the estimation procedure and the report generation.

My special thanks to UNICEF Bangladesh for providing support to prepare this report successfully. I hope this report will be helpful to support evidence-based policies, planning, and undertake in-depth analysis for development partners, NGOs, other practitioners, researchers and students.

Suggestions and comments for further improvement will be highly appreciated.

1. Introduction

1.1 Introduction

A child's family and home environment are crucial for their survival and development. However, outside education programs also play a vital role in giving children basic cognitive and language skills. Early childhood education forms the foundation for a high-quality basic education¹. Attending these programs or preschool can improve a child's readiness for primary school. Organized learning programs for children of one year younger than the official primary school entry age, support the SDG indicator 4.2.2². Investing in early childhood education can help bridge gaps, particularly for children with low social and economic status. Studies indicate that these investments have the highest returns for poorer children, acting as a pathway out of poverty or exclusion. Unfortunately, child marriage persists as a violation of human rights, especially in Bangladesh. The Sustainable Development Goals aim to eliminate child marriage by 2030, recognizing it as a harmful practice. Child marriage hampers girls' development, often leading to early pregnancy and social isolation. Pregnancy-related deaths are a significant cause of mortality for both married and unmarried girls aged 15 to 19³.

According to MICS, Bangladesh showed improvement in increasing participation in organized learning from 13.4% in 2012 to 77.4% in 2019. Moreover, Bangladesh achieved a reduction in women child marriage from 62% in 2012 to 53% in 2019. Despite these improvements, it is necessary to estimate the prevalence of these indicators at lower-level geographical areas so that more vulnerable areas can be targeted. This can be attempted through the technique of Small Area Estimation (SAE).

1.2 Administrative Units of Bangladesh

Bangladesh is divided into 8 Divisions and 64 Districts, although these have only a limited role in public policy. For local government, the country is divided into 580 Upazilas (sub-districts). The diagram below outlines the three tiers of government in Bangladesh.

Some knowledge exists on the general spatial pattern of organized learning for the child age five and child marriage of age 20 to 24 in Bangladesh. The MICS 2019 estimates prevalence of these indicators for the whole country, for each division and for each district. However, the accuracy of such estimates depends crucially on the effective sample size at that level. At upazila level, the standard errors of survey-based estimates become too large to be useful because each is based on a small number of observations.

1.3 Literature of SAE and SAE of Participation in Organized Learning and Child Marriage

During the last decade, globally, there has been a rising demand for (objective and subjective) progress and well-being indicators at a smaller delineation⁴. These measures are important because they are needed by the policymakers in planning and monitoring the effectiveness of their policies and programmes. This necessity has been intensified due to the fact that all the governments are mandated to a perpetual tracking and monitoring of the indicators of the SDG towards 2031. Effective targeting for the greater needed sub regions requires a nationwide overview of these indicator at the sub-division

⁴Ida Kubiszewski, Nabeeh Zakariyya, and Diane Jarvis (2019), Subjective wellbeing at different spatial scales for individuals satisfied and dissatisfied with life, PeerJ. 7. <https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6387756/>

level. Estimates need to be precise, i.e., with small standard errors, so that the areas with the greatest need are identified correctly. Therefore, to be informative and effective, the estimates of participation in organized learning and child marriage should also be chosen at the appropriate level of disaggregation. This analysis includes an investigation using Small Area Estimation (SAE) methods of how finely the estimates of participation in organized learning and child marriage may be disaggregated while maintaining an appropriate precision level.

Small Area Estimation is a mathematical and statistical method that models data collected from one or more data sources to produce estimates, such as poverty, that are more accurate at small area level than using only data collected from each small area.

In many such models, for the estimate for a particular small area, an additional accuracy is achieved by “extracting information” by using information from areas to which it is similar. As a result, combining data from different sources is a ploy used in some small area estimation techniques. New survey information, for example, maybe combined with census data to update estimates from the original census. In participation in organized learning and child marriage it is a common scenario that a statistical model is fitted to a survey data. This model is used to predict a variable whose data is not collected in the census, based on variables that are collected in both survey and census.

The World Bank method^{5,6}, also commonly called the ELL (Elbers, Lanjouw and Lanjouw) method, is the most common methodology for small area estimation of poverty and malnutrition in developing countries. Free software PovMap⁷ and PovMap 2⁸ are now available from the World Bank website. Variations of the ELL method has been implemented for the World Bank in a number of other countries, including Thailand⁹, South Africa¹⁰, Brazil¹¹, the Philippines¹², and for the World Food Programme in Bangladesh¹³, Nepal¹⁴, and Cambodia¹⁵.

Jones and Haslett¹⁴ have conducted the initial small area estimation of poverty and malnutrition in Bangladesh in 2003 for the UN World Food Programme. In 2010, from the Household Income and Expenditure Survey (HIES)¹⁶ poverty estimates were produced for the country at the division level, using poverty lines updated from the 2005 study using regional price indices. In a subsequent report by the World Bank¹⁷ (World Bank, 2013), this trend in poverty reduction is discussed and contrasted with the situation in health and nutrition outcomes. The World Bank analysis provides upazila-level estimates of economic poverty indicators, but not of undernutrition indicators. The HIES 2016 did not include anthropometric measures of children under five, so cannot be used to estimate stunting and underweight prevalence. Such measures are typically available only in surveys specifically focusing on health and nutrition.

In 2023, Small Area Estimates (SAE) of stunting, underweight and wasting in children under five years of age in Bangladesh are produced at upazila level by combining survey data from the Multiple Cluster Indicator Survey 2019 (MICS) and with auxiliary data derived from the Bangladesh Population and Housing Census 2011. The models have been applied to child level census data to estimate underweight, stunting and wasting at upazila level.

According to our knowledge, small area estimates of participation in organized learning and child marriage in Bangladesh have not been produced. Therefore, our main objective is to produce and map upazila-level estimates of participation in organized learning and child marriage in Bangladesh.

The statistical technique of small-area estimation is described in detail in the next section. Outputs, in the form of estimates at local level together with their standard errors, can be combined with Geographic Information System (GIS) location data to produce a small area estimate map for the whole country, giving a graphical summary of which areas are suffering relatively high deprivation.

1.4 Measures of Participation in Organized Learning and Child Marriage

In this study, the measures of Participation in Organized Learning are defined as the proportion of children age one year younger than the official primary school entry age at the beginning of the school year, by attendance to education, and attendance to an early childhood education programme or primary education. The child marriage is defined as the proportion women age 20-24 being married before age 18 and age 15.

1.5 Scope and Objectives

For most users, an atlas of maps is much more useful than a detailed technical report on small area estimation methodology, even if it also contains finer level tabulated detail. Our main purpose in producing maps of participation in organized learning and child marriage at upazila level is to aid the planning of development assistance programmes. They could, in addition, be helpful as a research tool, for example, by overlaying geographic, social, or economic indicators. The detailed tabulation of the upazila level estimates and maps are kept in a separated document in consideration of most of the user. This small area estimates will provide a detail perspective on geographical distribution child education and marriage.

2. Data and Methodology

2.1 Multiple Indicator Cluster Survey 2019

The Bangladesh Multiple Indicator Cluster Survey (MICS)¹⁸ was carried out in 2019 by the Bangladesh Bureau of Statistics (BBS) in collaboration with UNICEF Bangladesh, as part of the Global MICS Programme. During data collection, UNFPA Bangladesh has also provided a financial resource to undertake quality assurance visits. MICS surveys measured key indicators to generate data for use in policies, programmes, and national development plans, and monitor progress towards the Sustainable Development Goals (SDGs) and other internationally agreed-upon commitments.

2.2 Bangladesh Population and Housing Census 2011 (Census 2011)

The independent Bangladesh has conducted population census on a decennial basis since 1974. However, the history of census in this region goes back to 1872. The fifth Population and Housing Census of Bangladesh was conducted 15 - 19 March 2011. The main objective was to collect information on housing, households and population for development planning and human resource development programmes, and economic management.

The Bangladesh Bureau of Statistics (BBS) conducted the fifth Population and Housing Census of Bangladesh in 2011 under the United Nations conceptual framework. BBS started preparatory activity at the beginning of 2009 with updating of maps and area geo-codes. The census was conducted using the house to house interview method with a modified De-Facto method where floating population was enumerated at census night. Enumeration Areas (EA) were constructed using GIS mapping. On average, each Enumeration Area (EA) consisted of about 120 households. A total of 296 thousand EAs were constructed.

¹⁸Bangladesh Bureau of Statistics (BBS) and UNICEF Bangladesh. 2019. Progotir Pathey, Bangladesh Multiple Indicator Cluster Survey 2019, Survey Findings Report. Dhaka, Bangladesh.

file:///E:/consultancy/WFP/July21/Bangladesh%202019%20MICS%20Report_English.pdf

2.3 SAE Methodology

To theoretically place the SAE methodology, we begin with a target variable Y , for which we require estimates over a range of small subpopulations, usually corresponding to small geographical areas. In this report, Y is participation in organized learning and child marriage. Auxiliary information, denoted X , representing additional variables that have been measured for the whole population, either by a census or via a GIS database, can be used under some circumstances to improve the estimates. It is customary to relate the two variables Y and X in a regression setup as

$$\log\left(\frac{P(Y_{ijk}=1)}{1-P(Y_{ijk}=1)}\right) = X_{ijk}\beta + c_i + h_{ij} + e_{ijk} \quad (3.1)$$

where Y_{ijk} represents the measurement on the k th respondent in the j th household in the i th cluster, X_{ijk} represents the measurement on the fixed effects of the auxiliary variables for the k th under-five child in the j th household in the i th cluster c_i , while the other terms c_i , h_{ij} and e_{ijk} represent the random effects, c_i is the error term held in common by the i th cluster, h_{ij} the household level error within the cluster, and e_{ijk} the error within each sampled household. The relative importance of the three random effects can be measured by their respective variances σ_c^2 , σ_h^2 and σ_e^2 .

2.4 Selection of Auxiliary Data

For fitting the model (3.1), the first step is to identify and select the auxiliary data X to be used to predict the target variable Y . There could be two types of X variables: the survey variables, obtainable or derivable from the survey at household or individual level (in our case the MICS 2019), and area-level variables applying to particular geographic units that can be merged from other sources into the survey data using area codes (e.g., division, zila, upazila, union, mauza enumeration area codes). The latter includes means of census variables calculated at mauza level from the census data.

The choice of auxiliary variables should be done in a way that they are comparable in survey data and census data set. It can be done initially by examining the survey and census questionnaires. In consultation with BBS staff, a preliminary identification and matching of

common survey and census variables, was reported by Haslett, Jones and Isidro¹⁹ and in Small-Area Estimation of Child Undernutrition in Bangladesh, 2023.

Common variables were then subjected to statistical checks to ensure that the corresponding survey and census variables matched statistically as well as conceptually. In the case of categorical data we compare proportions in each category: for numerical data, such as the household proportion of females, we compare the means and standard deviations.

2.5 Fitting the First Stage Model

The fitting of models for participation in organized learning and child marriage using the MICS 2019 data requires the design variables from the survey to produce unbiased estimates with the correct standard errors. Survey weights for the MICS 2019 data are available in the data set used for all summary computations using the MICS 2019 dataset.

Choosing an optimal model for (3.2) is a complex problem because we have a large number of possible predictor variables (25 - see Appendix A). There is also the case of the presence of multicollinearity because of the inter-relation among these variables. If interactions among the variables are considered, the number of variables becomes unusually large. Consideration of a second order interactions, if not higher order, is a requirement to take into account the district distinguishability. However, over-fitting the model in this phase of the inclusion of variables should be avoided, so the number of predictors included in the model is small compared to the number of observations in the survey. Still, there is also the problem of selecting a few variables from the large number available, which appear to be useful, only to find that an apparently strong statistical relationship in the survey data does not hold for the population as a whole. We employ automated search to avoid losing important variables and/or over-fitting the model. A step-wise selection of variables is considered for this purpose.

Some implementations of ELL methodology have fitted separate models for each stratum defined by the survey design. However, Small-Area Estimation of Child Malnutrition in Bangladesh, 2014²⁰ has employed an overall model arguing against the strata-wise fitting. The strata-wise fitting has the advantage of tailoring the model to account for the different

¹⁹Haslett, S., Jones, G. and Isidro, M. (2014) Potential for Small Area Estimation of Undernutrition at sub-District Level in Bangladesh: Interim Feasibility Report to UN World Food Programme, Massey University, New Zealand, February 2014.

²⁰Bangladesh Bureau of Statistics, Small-Area Estimation of Child Undernutrition in Bangladesh, 2014.

characteristics of each stratum, but it can increase the problem of over-fitting if some strata are small. We initially chose to try for one model across the whole country, and then use regional interaction terms as necessary to allow for modelling differences between regions. This has the advantage of more stable parameter estimates and a better chance of finding genuine relationships that apply outside of the estimation data. The fitting of separate models to different strata, or areas such as districts, is related (but not identical) to the intermediate option of including explicit district-level effects in an overall model.

Appendix B contains the relevant statistics for the final models for participation in organized learning and child marriage. Sensitivity and specificity for each model is considered for model diagnostics.

2.6 Variance Modelling

Participation in organized learning and child marriage were modelled slightly differently to take into account the expected correlation in these measures between children and women in the same household. The variance components, σ_c^2 , σ_h^2 and σ_e^2 of the respective components can be estimated by restricted maximum likelihood (REML), for methodological details, see Laird and Ware²¹ and Robinson²². In this study we use the simpler parametric bootstrap approach, sampling from normal distributions with variances set to the estimated variance components. There should be little difference in practice as estimation with this many levels encourages approximate normality in the residuals.

2.7 Simulation of Predicted Values

A total of 100 bootstraps predicted values Y_{ij}^b were produced for each child age 5 or women age 20-24 in the census for each target variable, as described in Section 3.4. For the three-level models, height-for-age, weight-for-age and weight-for-height, this was amended slightly to

$$Y_{ijk}^b = X_{ijk}\hat{\beta}^b + c_i^b + h_{ij}^b + e_{ijk}^b, \quad b=1, 2, \dots, B$$

²¹Laird, N.M. and Ware, J.H. (1982). Random-effects models for longitudinal data, *Biometrics*, 38, 963 - 974.

²²Robinson, G.K. (1991) That BLUP is a good thing: the estimation of random effects, *Statistical Science*, 6, 15-51.

with the residuals at each level c_i^b , h_{ij}^b , e_{ijk}^b they were drawn independently from normal distributions with mean zero and variances equal to the estimated variance components from the regression analysis.

2.8 Production of Final Estimates

The predicted probabilities for each child and women from the census can then be assessed as being have organized learning and being child marriage and each of these measures separately grouped at the appropriate geographic level. Our main target is upazila-level small-area estimates, but we have also considered higher levels of aggregation (division, and district), compared with the direct survey estimates. For example, the estimated prevalence of stunting for small area R is:

$$OL_R^b = \sum_{\substack{i,j \in R \\ ij \in R}} I(Prob_{ij}^b > threshold) / N_R$$

where N_R is the number of eligible children in R .

The 100 bootstrap estimates for each small area, e.g. $S_R^1, S_R^2, \dots, S_R^{100}$ were summarized by their mean and standard deviation, giving a point estimate and a standard error for each indicators at each small area.

3. Results for Participation in Organized Learning and Child Marriage

The direct estimates at district level participation in organized learning for the child age 5 and child marriage for the women age 20-24 available from the MICS 2019 were used to check and compare the corresponding estimates obtained from the SAE methodology. Appendix Tables C.1 and C.2 shows both sets of district estimates together with their standard errors (se). The standard errors for the direct survey estimates have been taken from the reported values in the MICS 2019 report. The standard errors for the Small Area Estimates (SAE) are the standard deviations of the 100 bootstrap estimates.

We have added a standardized difference between the two sets (direct estimate and SAE), defined as

$$Z = \frac{\text{Small area estimate} - \text{direct estimate}}{\sqrt{(\text{small area estimate se})^2 + (\text{direct estimate se})^2}}$$

If both methods are correctly estimating the same quantities, then Z should approximate a standard normal distribution.

It should be noted that there is not enough reduction in standard error from the small-area methodology at the largest levels (divisions) of aggregation, but in all cases, the SAEs are more precise (i.e. smaller standard errors) than the direct estimates. This is because the uncertainty in the direct estimates due to sampling variability is replaced by uncertainty in the estimated model for the SAEs. At the lower levels however the improvement in precision is much more dramatic.

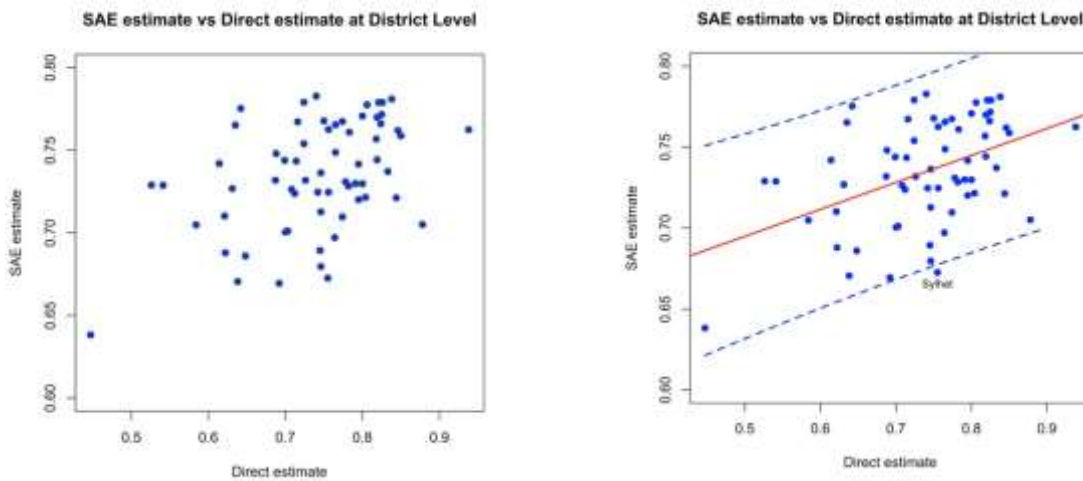

3.1 Results for Participation in Organized Learning

From Table C.1, we can see that small area estimates of participation in organized learning are almost close to the direct estimates at district level with on average 6% absolute differences. The left panel of Figure 3.1 shows the scatter plot of district level small area estimates against the corresponding direct estimates. The scatter plot is shown to identify if the two sets of estimates are similar by observing the proximity of the scatter plot around the 45-degree straight line. The right panel of the graph shows straight line fit of the two sets of estimates along with the 95% confidence band. According to the Figure 3.1, all the SAE

estimates for all the districts except Sylhet are within 95% confidence band of the direct estimates. The SAE of Sylhet has been identified as a little bit underestimated than the direct estimates. Overall, the SAE shows a strong level of agreement between the district level estimates with the direct estimates.

The overall agreement between the two methods can be checked in Figure 3.2, where the Z scores were plotted in a Q-Q plot that depicts a straight line indicating that the Z scores follow a near standard normal distribution. Moreover, the magnitude of the standardized values is well within three-standard deviation limits (<3.0) except for two districts (Jashore and Noakhali).

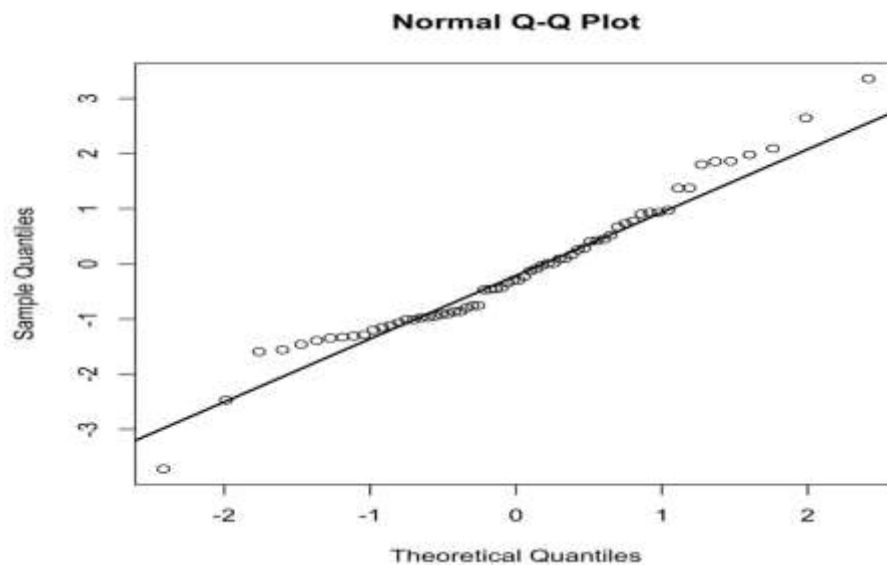

Figure 3.1 Scatter Plot of District Level Small Area Estimates of Participation in Organized Learning

Scatter plot of district level small area estimates of participation in organized learning against the corresponding direct estimates

Straight line fit of the two sets of estimates along with the 95% confidence band

Figure 3.2 Q-Q Plot of the Z-score Computed for Comparison Between SAE of Participation in Organized Learning for District Against the District Estimates Provided in MICS 2019

Hence, we may conclude that the SAE for districts is as good as the direct estimates provided in the MICS 2019. For our study, the comparison is very straightforward since MICS 2019 produced district estimates with moderately acceptable sample sizes.

Table C.1 indicates that the small-area estimates of participation in organized learning have similar standard errors compared to the direct estimates from the surveys at high aggregation levels (districts).

The district-level estimates of participation in organized learning are summarized in Table 3.1. It is observed that the standard errors are quite small, with an average of only 4%. The SAE estimates of participation in organized learning ranges from 64% to 78% while the direct estimates range from 45% to 94%. A complete listing of the estimates is given in Appendix C.

Table 3.1 Summary of District-Level Estimates of Participation in Organized Learning Prevalence

	Minimum	Maximum	Median	Mean	Std. Deviation	95% Percentile	
						Lower	Upper
Direct Estimate	0.447	0.938	0.752	0.74	0.089	0.496	0.901
Std Error	0.03	0.059	0.049	0.049	0.006	0.031	0.059
SAE Estimate	0.638	0.783	0.734	0.735	0.033	0.657	0.782
Std Error	0.02	0.087	0.039	0.042	0.012	0.022	0.075

Table 3.2 shows the summary of the upazila level estimates of participation in organized learning. It is remarkable that even at upazila level, where standard errors would be expected to be higher, the prevalence have reasonably similar standard errors in comparison with the variability of the small area estimates between the upazila. This indicates that upazila level estimates can generally be distinguished from one another even allowing for modelling errors. The SAE estimates of the participation in organized learning have an average standard error of 4%. The SAE estimates of participation in organized learning at upazila level range from 63% to 80% while the direct estimates range from 0% to 100%.

Table 3.2 Summary of Upazila-Level Estimates of Participation in Organized Learning Prevalence

	Minimum	Maximum	Median	Mean	Std. Deviation	95% Percentile	
						Lower	Upper
Direct estimate	0	1	0.75	0.733	0.21	0.2	1
Std Error	0	0.5	0.133	0.142	0.101	0	0.333
SAE Estimate	0.625	0.796	0.734	0.732	0.033	0.664	0.783
Std Error	0.011	0.098	0.04	0.041	0.015	0.014	0.074

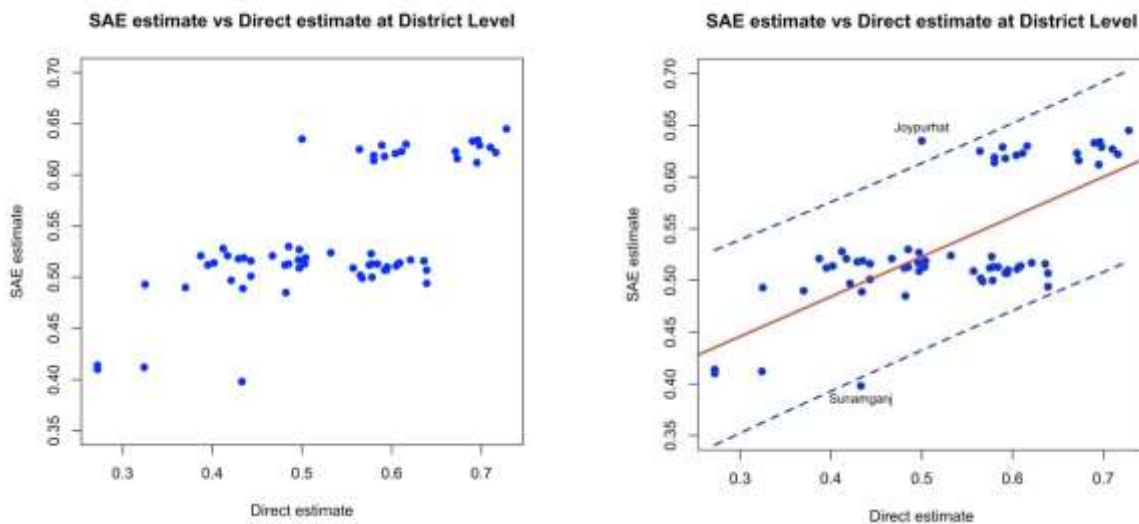

3.2 Results for Child Marriage of Before 18

As like the estimates of participation in organized learning, the SAE estimates of child marriage before age 18 are compared with the estimates from MICS 2019. This comparison is also listed in Table C.2. From Table C.2, we can see that the small-area estimates of child marriage before age 18 are all more or less close to the direct estimates at the district level with 7% average absolute difference. The left panel of Figure 3.3 shows the scatter plot of district level small area estimates against the corresponding direct estimates. This plot is shown to see the agreement between the two sets of estimates, and the proximity of the scatter plot around the 45-degree straight line indicates a strong agreement. The right panel of

the graph shows straight line fit of the two sets of estimates along with the 95% confidence band for the direct estimates. This figure demonstrates that all the SAE for all the districts except Joypurhat and Sunamganj are within the 95% confidence band of the direct estimates. The SAE of Kurigram is slightly under estimated and the SAE of the Sunamganj are overestimated. These again shows a strong level of agreement between the individual district estimates by the two methods.

The overall agreement between the two methods can be checked in Figure 3.4, where the Z scores were plotted in a Q-Q plot that depicts a straight line indicating that the Z scores follow a near standard normal distribution. Moreover, the magnitude of the standardized values are well within three-standard deviation limits (<3.0) except for few districts.

Figure 3.3 Scatter Plot of District Level Small Area Estimates of Child Marriage of Age Before 18

Scatter plot of district level small area estimates of Child marriage of age before 18 against the corresponding direct estimates

Straight line fit of the two sets of estimates along with the 95% confidence band

Figure 3.4 Q-Q Plot of the Z-Score Computed for Comparison Between SAE of Child Marriage of Age Before 18 for District Against the District Estimates Provided in MICS 2019

The district-level estimates for child marriage before age 18 are summarized in Table 3.3. The estimates seem to have smaller standard errors to those for participation in organized learning, having an average of only 2.2%. The SAE estimate of child marriage before age 18 range from 40% to 65% while the direct estimate ranges from 27% to 73%. A complete listing of the estimates is given in Appendix C.

Table 3.3 Summary of District-Level Estimates of Child Marriage of Age Before 18 Prevalence

	Minimum	Maximum	Median	Mean	Std. Deviation	95% Percentile	
						Lower	Upper
Direct Estimate	0.272	0.728	0.566	0.536	0.111	0.272	0.721
Std Error	0.024	0.046	0.04	0.039	0.004	0.024	0.045
SAE Estimate	0.398	0.645	0.516	0.537	0.062	0.405	0.639
Std Error	0.009	0.042	0.022	0.022	0.006	0.009	0.038

Again, at upazila level the standard errors for child marriage before age 18 prevalence are reasonably small, as shown in Table 3.4 with an average of 2.2%. The estimated prevalence of child marriage before age 18 at upazila level ranges from 38% to 68%.

Table 3.4 Summary of Upazila-Level Estimates of Child Marriage of Age Before 18 Prevalence

	Minimum	Maximum	Median	Mean	Std. Deviation	95% Percentile	
						Lower	Upper
Direct estimate	0	1	0.519	0.526	0.185	0.167	0.883
Std Error	0	0.5	0.118	0.131	0.058	0.061	0.289
SAE Estimate	0.383	0.657	0.517	0.533	0.06	0.404	0.637
Std Error	0.006	0.051	0.022	0.022	0.008	0.007	0.039

3.3 Results for Child Marriage of Age Before 15

The SAE estimates of child marriage before age 15 are also compared with the estimates from MICS 2019. This comparison is again listed in Table C.3. From Table C.3, we can see that the small-area estimates of child marriage before age 15 are all more or less close to the direct estimates at the district level with 4% average absolute difference. The left panel of Figure 3.5 shows, the scatter plot of district level small area estimates against the corresponding direct estimates. This plot is shown to see the agreement between the two sets of estimates, and the proximity of the scatter plot around the 45-degree straight line indicates a strong agreement. The right panel of the graph shows straight line fit of the two sets of estimates along with the 95% confidence band for the direct estimates. This figure demonstrates that all the SAE for all the districts except Joypurhat, Sunamganj and Bogura are within the 95% confidence band of the direct estimates. The SAE of these three districts is overestimated. These again shows a strong level of agreement between the individual district estimates by the two methods.

The overall agreement between the two methods can be checked in Figure 3.6, where the Z scores were plotted in a Q-Q plot that depicts a straight line indicating that the Z scores follow a near standard normal distribution. Moreover, the magnitude of the standardized values is well within three-standard deviation limits (<3.0) except for three districts (Chapainawabganj, Chattogram and Sylhet).

Figure 3.5 Scatter Plot of District Level Small Area Estimates of Child Marriage of Age Before 15

scatter plot of district level small area estimates of child marriage of age before 15 against the corresponding direct estimates

straight line fit of the two sets of estimates along with the 95% confidence band

Figure 3.6 Q-Q Plot of the Z-Score Computed for Comparison Between SAE of Child Marriage of Age Before 15 for District Against the District Estimates Provided In MICS 2019

The district-level estimates for child marriage before age 15 are summarized in Table 3.5. The estimates seem to have smaller standard errors to those for participation in organized learning and child marriage before age 18, having an average of only 0.9%. The SAE estimate of child marriage before age 15 at district level range from 11% to 20% while the direct estimate ranges from 5% to 39%. A complete listing of the estimates is given in Appendix C.

Table 3.5 Summary of District-Level Estimates of Child Marriage of Age Before 15 Prevalence

	Minimum	Maximum	Median	Mean	Std. Deviation	95% Percentile	
						Lower	Upper
Direct Estimate	0.05	0.39	0.1485	0.161	0.065	0.058	0.348
Std Error	0.013	0.042	0.028	0.028	0.006	0.013	0.04
SAE Estimate	0.11	0.202	0.153	0.157	0.021	0.112	0.201
Std Error	0.003	0.016	0.009	0.009	0.002	0.003	0.001

Again, at upazila level the standard errors for the prevalence of child marriage before age 15 are reasonably small, as shown in Table 3.6 with an average of 0.9%. The estimated prevalence of child marriage before age 15 at upazila level ranges from 7.5% to 21%.

Table 3.6 Summary of Upazila-Level Estimates of Child Marriage of Age Before 15 prevalence

	Minimum	Maximum	Median	Mean	Std. Deviation	95% Percentile	
						Lower	Upper
Direct estimate	0.026	0.8	0.167	0.184	0.114	0.041	0.479
Std Error	0.026	0.5	0.088	0.101	0.056	0.035	0.227
SAE Estimate	0.075	0.211	0.152	0.155	0.022	0.111	0.202
Std Error	0.003	0.02	0.111	0.009	0.003	0.004	0.016

3.4 Maps for Participation in Organized Learning and Child Marriage

Maps of the participation in organized learning estimates are given in Appendix D.2. Maps for child marriage before age 18 are in Appendix D.3. Maps for child marriage before age 15 are in Appendix D.4.

4. Conclusion and Discussion

In this report, upazila-level estimates of participation in organized learning for the child age 5 and child marriage for the women age 20-24 have been produced and mapped in Bangladesh. The small-area estimation methodology combines survey data from the Multiple Indicator Cluster Survey (MICS 2019) with auxiliary data derived from the 2011 Population and Housing Census. For participation in organized learning, a single model that includes division-level effects was adopted, proving adequate for predicting a child's participation in organized learning. Similarly, a single model for child marriage was found to be adequate for predicting a woman's likelihood of child marriage. The small-area estimates obtained for each indicator showed acceptably similar standard errors to direct estimates. Sensitivity and specificity were used as measures of model diagnostics, with good results for the model of participation in organized learning and moderate results for child marriage before age 18. However, the model for child marriage before age 15 exhibited good sensitivity but lower specificity. The small-area estimates generated in this report have low standard errors up-to the upazila level and district-level estimates generally align with those obtained by MICS 2019, with a few exceptions. For participation in organized learning in Sylhet district, the estimate was under-estimated, while for child marriage before age 18, Joypurhat was over-estimated and Sunamganj was under-estimated. The model fitted to district estimates of child marriage before age 15 appeared to over-estimate the districts of Joypurhat, Sunamganj and Bogura. It's important to note that where the model provided over or underestimations for district estimates, similar tendencies are likely in the upazila-level estimates under those districts. This is evident in the upazila estimates of participation in organized learning in the upazilas of Sylhet district, which are relatively lower. The variables used may have contributed to these lower values for the peripheral upazilas of Sylhet. Small-area estimation works best in aggregate, so when using individual-level estimates for upazilas in flagged districts for policy purposes, caution should be exercised.

5. Appendices

A. Potential Auxiliary Variables

Table A.1 Child- and Household-Level Variables in MICS 2019 and Census 2011

Sl.	Variable name
1	Gender
2	Child age0-11 months
3	Child age12-23 moths
4	Child age24-35 months
5	Child age36-47 months
6	Child age48-59 months
7	Log of household size
8	HH has electricity
9	HH head has secondary education
10	HH head married or other than married
11	Proportion of adult female in household
12	Proportion of child age 7-14 in household
13	Kitchen separate household
14	HH has electricity, urban
15	HH head married or other than married, urban
16	Proportion of adult female in household, urban
17	Proportion of household own land for agriculture in mauza
18	Proportion of household has no toilet facility in mauza
19	Proportion of child age 7-14 has literacy in mauza
20	Proportion household has pukka or semi pukka structure in mauza
21	Mother has at least secondary education
22	Poverty rate district wise
23	Aman production district wise
24	Aus production district wise
25	Boro production district wise

Note: NA means not available. NA- for the upazila whose codes are not available in the census and we cannot generate its SAE estimates.

Zero values in direct estimate in Upazilas means no samples are there in that upazila

Note: NA means not available. NA- for the upazila whose codes are not available in the census and we cannot generate its SAE estimates.

Zero values in direct estimate in Upazilas means no samples are there in that upazila
